

# csci 210: Data Structures

## Trees

# Summary

## ■ Topics

- general trees, definitions and properties
- interface and implementation
- tree traversal algorithms
  - depth and height
  - pre-order traversal
  - post-order traversal
- binary trees
  - properties
  - interface
  - implementation
- binary search trees
  - definition
  - h-n relationship
  - search, insert, delete
  - performance

## ■ READING:

- LC textbook chapter on Trees and Binary Search Trees

# Trees

- So far we have seen linear structures
  - linear: before and after relationship
  - lists, vectors, arrays, stacks, queues, etc
- Non-linear structure: trees
  - probably the most fundamental structure in computing
  - hierarchical structure
  - Terminology: from family trees (genealogy)

# Trees

- store elements hierarchically
- the top element: root
- except the root, each element has a parent
- each element has 0 or more children

# Trees

## ■ Definition

- A tree  $T$  is a set of nodes storing elements such that the nodes have a parent-child relationship that satisfies the following:
  - if  $T$  is not empty,  $T$  has a special tree called the root that has no parent
  - each node  $v$  of  $T$  different than the root has a unique parent node  $w$ ; each node with parent  $w$  is a child of  $w$

## ■ Recursive definition

- $T$  is either empty
- or consists of a node  $r$  (the root) and a possibly empty set of trees whose roots are the children of  $r$

## ■ Terminology

- siblings: two nodes that have the same parent are called siblings
- internal nodes: nodes that have children
- external nodes or leaves: nodes that don't have children
- ancestors
- descendants

# Trees

root

internal nodes

leaves

# Trees

ancestors of u

# Trees

descendants of u

# Application of trees

- Applications of trees
  - class hierarchy in Java
  - file system
  - storing hierarchies in organizations

# Tree ADT

- Whatever the implementation of a tree is, its interface contains the following
  - root()
  - size()
  - isEmpty()
  - parent(v)
  - children(v)
  - isInternal(v)
  - isExternal(v)
  - isRoot()

# Tree Implementation

```
class Tree {  
    TreeNode root;  
  
    //tree ADT methods..  
}  
  
class TreeNode<Type> {  
    Type data;  
    int size;  
    TreeNode parent;  
    TreeNode firstChild;  
    TreeNode nextSibling;  
  
    //TreeNode methods  
    getParent();  
    getChild();  
    getNextSibling();  
    ...  
}
```

# Tree implementation

- Given tree implementation above, sketch the implementation for:
  - root()
  - size()
  - isEmpty()
  - parent(v)
  - children(v)
  - isInternal(v)
  - isExternal(v)
  - isRoot()

# Algorithms on trees: Depth

## Depth:

- $\text{depth}(T, v)$  is the number of ancestors of  $v$  in  $T$ , excluding  $v$  itself

## Recursive formulation

- if  $v == \text{root}$ , then  $\text{depth}(v) = 0$
- else,  $\text{depth}(v)$  is  $1 + \text{depth}(\text{parent}(v))$

Sketch how to compute the depth of a node  $v$  in tree  $T$ : `int depth(T, v)`

```
int depth(T, v) {
    if T.isRoot(v) return 0;
    return 1 + depth(T, T.parent(v));
}
```

## Analysis:

- $O(\text{number of ancestors of } v) = O(\text{depth of } v)$
- In the worst case the path is a linked-list and  $v$  is the leaf
- $\implies O(n)$ , where  $n$  is the number of nodes in the tree

# Algorithms on trees: Height

## Height:

- height of a node  $v$  in  $T$  is the length of the longest path from  $v$  to any leaf in  $T$

## Recursive formulation:

- if  $v$  is leaf, then its height is 0
- else  $\text{height}(v) = 1 + \text{maximum height of a child of } v$

Definition: The height of a tree is the height of its root.

Height and depth are “symmetrical”

Proposition: the height of a tree  $T$  is the maximum depth of one of its leaves.

Sketch how to compute the height of tree  $T$ :  $\text{int height}(T,v)$

# Height

## Algorithm:

```
int height(T,v) {  
    if T.isExternal(v) return 0;  
    int h = 0;  
    for each child w of v in T do  
        h = max(h, height(T, w))  
    return h+1;  
}
```

## Analysis:

- total time: the sum of times spent at all nodes in all recursive calls
- the recursion:
  - v calls height(w) recursively on all children w of v
  - height() will eventually be called on every descendant of v
  - overall: height() is called on each node precisely once, because each node has one parent
- aside from recursion
  - for each node v: go through all children of v
    - $O(1 + c_v)$  where  $c_v$  is the number of children of v
  - over all nodes:  $O(n) + \text{SUM}(c_v)$ 
    - each node is child of only one node, so its processed precisely once as a child
    - $\text{SUM}(c_v) = n - 1$
- total:  $O(n)$ , where n is the number of nodes in the tree

# Tree traversals

- A traversal is a systematic way to visit all nodes of  $T$ .
- pre-order: root, children
  - parent comes before children; overall root first
- post-order: children, root
  - parent comes after children; overall root last

```
void preorder(T, v)
    visit v
    for each child w of v in T do
        preorder(w)
```

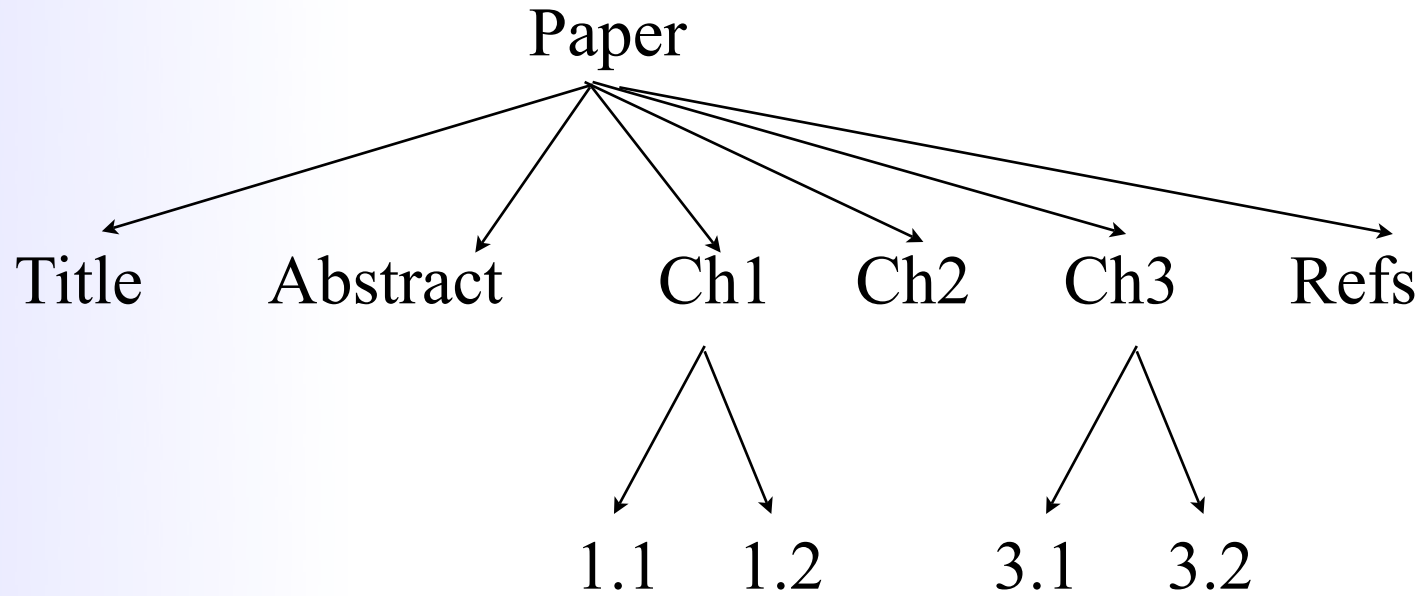

```
void postorder(T, v)
    for each child w of v in T do
        postorder(w)
    visit v
```

□ Analysis:  $O(n)$  [same arguments as before]

# Examples

- Tree associated with a document

- In what order do you read the document?

## Example

- Tree associated with an arithmetical expression

- Write a method that evaluates the expression. In what order do you traverse the tree?

# Binary trees

# Binary trees

■ **Definition:** A binary tree is a tree such that

- every node has at most 2 children
- each node is labeled as being either a left child or a right child

■ **Recursive definition:**

- a binary tree is empty;
- or it consists of
  - a node (the root) that stores an element
  - a binary tree, called the left subtree of T
  - a binary tree, called the right subtree of T

■ **Binary tree interface**

- left(v)
- right(v)
- hasLeft(v)
- hasRight(v)
- + isInternal(v), is External(v), isRoot(v), size(), isEmpty()

# Properties of binary trees

## ■ In a binary tree

- level 0 has  $\leq 1$  node
- level 1 has  $\leq 2$  nodes
- level 2 has  $\leq 4$  nodes
- ...
- level  $i$  has  $\leq 2^i$  nodes

■ Proposition: Let  $T$  be a binary tree with  $n$  nodes and height  $h$ . Then

- $h+1 \leq n \leq 2^{h+1} - 1$
- $\lg(n+1) - 1 \leq h \leq n-1$

# Binary tree implementation

- each node points to its left and right children ; the tree stores the root node and the size of the tree
- sketch how to implement the following functions:
  - left(v)
  - right(v)
  - hasLeft(v)
  - hasRight(v)
  - isInternal(v)
  - is External(v)
  - isRoot(v)
  - size()
  - isEmpty()
- next
  - insertLeft(v,e)
  - insertRight(v,e)
  - remove(e)
  - addRoot(e)

# Binary tree operations

- `insertLeft(v,e)`:
  - create and return a new node  $w$  storing element  $e$ , add  $w$  as the left child of  $v$
  - an error occurs if  $v$  already has a left child
  
- `insertRight(v,e)`
  - similar
  
- `remove(v)`:
  - remove node  $v$ , replace it with its child, if any, and return the element stored at  $v$
  - an error occurs if  $v$  has 2 children
  
- `addRoot(e)`:
  - create and return a new node  $r$  storing element  $e$  and make  $r$  the root of the tree;
  - an error occurs if the tree is not empty
  
- `attach(v,T1, T2)`:
  - attach  $T1$  and  $T2$  respectively as the left and right subtrees of the external node  $v$
  - an error occurs if  $v$  is not external

# Performance

- all  $O(1)$ 
  - left(v)
  - right(v)
  - hasLeft(v)
  - hasRight(v)
  - isInternal(v)
  - is External(v)
  - isRoot(v)
  - size()
  - isEmpty()
  - addRoot(e)
  - insertLeft(v,e)
  - insertRight(v,e)
  - remove(e)

# Binary tree traversals

- Binary tree computations often involve traversals
  - pre-order: root left right
  - post-order: left right root
- Additional traversal for binary trees
  - in-order: left root right
    - visit the nodes from left to right
- Exercise:
  - write methods to implement each traversal on binary trees

# Application: Tree drawing

- Come up with a solution to “draw” a binary tree in the following way. Essentially, we need to assign coordinate  $x$  and  $y$  to each node.
  - node  $v$  in the tree
    - $x(v) = ?$
    - $y(v) = ?$

## Application: Tree drawing

- We can use an in-order traversal and assign coordinate  $x$  and  $y$  of each node in the following way:
  - $x(v)$  is the number of nodes visited before  $v$  in the in-order traversal of  $v$
  - $y(v)$  is the depth of  $v$

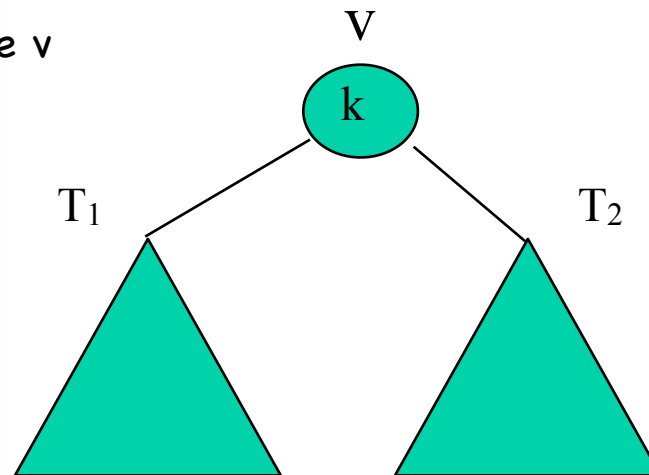

# Binary tree searching

- write `search(v, k)`
  - search for element `k` in the subtree rooted at `v`
  - return the node that contains `k`
  - return null if not found
  
- performance
  - ?

# Binary Search Trees (BST)

- **Motivation:**
  - want a structure that can search fast
  - arrays: search fast, updates slow
  - linked lists: search slow, updates fast
- **Intuition:**
  - tree combines the advantages of arrays and linked lists
- **Definition:**
  - a BST is a binary tree with the following "search" property

- for any node  $v$

allows to search efficiently

all nodes in  $T_1 \leq k$

all node in  $T_2 > k$

# BST

- Example

# Sorting a BST

- Print the elements in the BST in sorted order

# Sorting a BST

- Print the elements in the BST in sorted order.

```
//print the elements in tree of v in order  
sort(BSTNode v)  
    if (v == null) return;  
    sort(v.left());  
    print v.getData();  
    sort(v.right());
```

- in-order traversal: left -node-right
- Analysis:  $O(n)$

# Searching in a BST

# Searching in a BST

```
//return the node w such that w.getData() == k or null if such a node  
//does not exist  
BSTNode search (v, k)  {  
    if (v == null) return null;  
    if (v.getData() == k) return v;  
    if (k < v.getData()) return search(v.left(), k);  
    else return search(v.right(), k)  
}
```

## ■ Analysis:

- search traverses (only) a path down from the root
- does NOT traverse the entire tree
- $O(\text{depth of result node}) = O(h)$ , where  $h$  is the height of the tree

# Inserting in a BST

- insert 25

# Inserting in a BST

- insert 25
  - There is only one place where 25 can go

- `//create and insert node with key k in the tree`
- ```
void insert (v, k) {  
    //this can only happen if inserting in an empty tree  
    if (v == null) return new BSTNode(k);  
    if (k <= v.getData()) {  
        if (v.left() == null) {  
            //insert node as left child of v  
            u = new BSTNode(k);  
            v.setLeft(u);  
        } else {  
            return insert(v.left(), k);  
        }  
    } else //if (v.getData() > k) {  
        ...  
    }  
}
```

# Inserting in a BST

- Analysis:
  - similar with searching
  - traverses a path from the root to the inserted node
  - $O(\text{depth of inserted node})$
  - this is  $O(h)$ , where  $h$  is the height of the tree

# Deleting in a BST

- delete 87
- delete 21
- delete 90

- case 1: delete a  
  - if  $x$  is left of its parent, set  $\text{parent}(x).\text{left} = \text{null}$
  - else set  $\text{parent}(x).\text{right} = \text{null}$
- case 2: delete a node with one child  
  - link  $\text{parent}(x)$  to the child of  $x$
- case 2: delete a node with 2 children  
  - ??

# Deleting in a BST

- delete 90

- copy in u 94 and delete 94
  - the left-most child of right(x)
- or
- copy in u 87 and delete 87
  - the right-most child of left(x)

← node has  $\leq 1$  child

← node has  $\leq 1$  child

# Deleting in a BST

- Analysis:
  - traverses a path from the root to the deleted node
  - and sometimes from the deleted node to its left-most child
  - this is  $O(h)$ , where  $h$  is the height of the tree

# BST performance

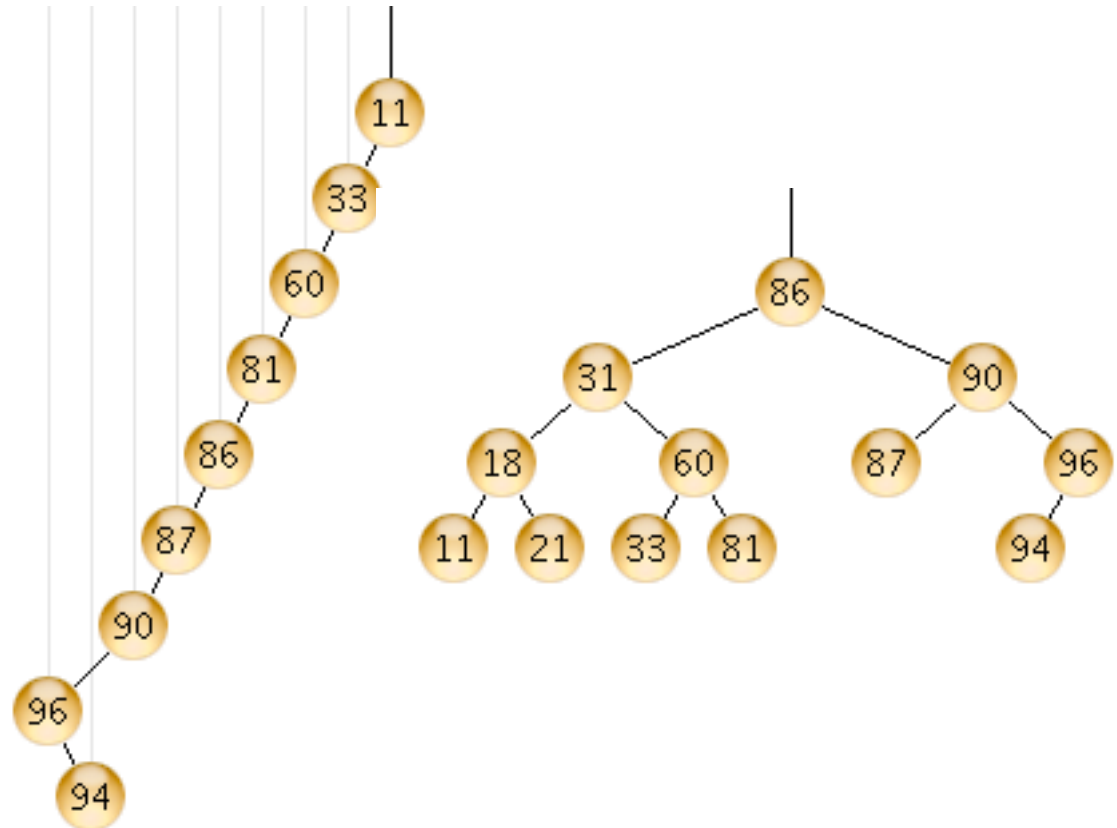

- Because of search property, all operations follow one root-leaf path
  - insert:  $O(h)$
  - delete:  $O(h)$
  - search:  $O(h)$

- We know that in a tree of  $n$  nodes

- $h \geq \lg(n+1) - 1$
- $h \leq n-1$

- So in the worst case  $h$  is  $O(n)$

- BST insert, search, delete:  $O(n)$
- just like linked lists/arrays

# BST performance

- **worst-case scenario**
  - start with an empty tree
  - insert 1
  - insert 2
  - insert 3
  - insert 4
  - ...
  - insert n
- **it is possible to maintain that the height of the tree is  $\Theta(\lg n)$  at all times**
  - by adding additional constraints
  - perform rotations during insert and delete to maintain these constraints
- **Balanced BSTs:  $h$  is  $\Theta(\lg n)$** 
  - Red-Black trees
  - AVL trees
  - 2-3-4 trees
  - B-trees
- **to find out more.... take csci231 (Algorithms)**
